This report documents an analysis performed for the Air Force Flight Dynamics Laboratory by the Aerospace Structures Information and Analysis Center, which is operated for the Air Force by Anamet Laboratories, Inc., under Contract No. F33615-75-C-3089. This work was designated as Problem No. 49. The AFFDL project monitor was J. R. Johnson.

I. INTRODUCTION

The analysis presented in this report is concerned with the effect of residual stresses on the life-lengthening of structural members. In particular, it has been observed that in specimens subjected to compressive residual stresses, which occur as a result of plastic deformation at a stress concentration, the life of the specimen is extended (Ref. 1-4). However, in some later tests involving both load and time effects, the residual compressive stresses have been shown to shorten the specimen lifetime (Ref. 5). This apparent contradiction is no doubt due to the complex phenomenological behavior of the material which is not very well understood at the present time.

To better understand the material behavior as discussed briefly above (and referred to as load-time dependent relaxation of residual stresses) an analytical approach has been developed to complement the existing experimental approaches. The techniques involved and the results of this analysis are presented in Section II. The conclusions and recommendations are presented in Section III. The supporting documentation for this analysis is included in the Appendices.

II. DISCUSSION OF RESULTS

The test specimen made of aluminum 7075 T651 (bare) and shown in Figure 1 has been used in this analysis. Creep test data for this specimen geometry and material have been made available to ASIAC (Ref. 6). To analyze this specimen the computer code CREEP-PLAST (Ref. 7) has been used. CREEP-PLAST is a two-dimensional finite element code for the creep and plasticity analysis of metal structures operating at high temperatures.

CREEP-PLAST considers instantaneous time-independent elastic-plastic and time-dependent creep simultaneously in an incremental procedure which requires the user to select his own discrete time and/or load increments. The method of calculation is based on the assumption that the total strain at any instant consists of elastic, plastic, and creep parts with essentially no interdependence between the plastic and creep components. The program is capable of predicting deformations, stresses, and total accumulated strains as functions of time and/or load for user specified thermal and mechanical loadings which can be varied independently.

A more detailed discussion of the capabilities of the CREEP-PLAST code can be found in Ref. 7.

For the prediction of creep strains, the user must first specify the creep strain as a function of the three parameters ϵ_t , $\dot{\epsilon}_m$ and r , which are then used in the following relation:

$$\epsilon_c = \epsilon_t(1 - e^{-rt}) + \dot{\epsilon}_m t$$

where

ϵ_t = limiting primary creep strain

r = exponential term in primary creep term

$\dot{\epsilon}_m$ = secondary creep strain rate

ϵ_c = creep strain

t = time

Note: All dimensions are in inches.

Figure 1 Aluminum 7075 T651 (Bare) Test Specimen Geometry

Once the quantities ϵ_t , $\dot{\epsilon}_m$ and r have been determined for each creep test at a different stress level it is necessary to express these quantities (ϵ_t , $\dot{\epsilon}_m$ and r) as functions of the stress level. The actual creep test data reduction and procedures required to determine ϵ_t , $\dot{\epsilon}_m$ and r as a function of the stress level are explained fully in Appendix A. The implementation of these relations just discussed requires that the user modify Subroutine SHIFT in CREEP-PLAST. The modifications to Subroutine SHIFT are included in Appendix B.

Also it is necessary to express the tangent modulus as a function of the stress level. To do this a representative stress-strain curve from MIL-HDBK-5 has been used. This stress-strain curve is then fitted with a polynomial of the form

$$\epsilon = a + b\sigma + c\sigma^2 + d\sigma^3$$

from which the tangent modulus (E_t) is derived.

$$\frac{\partial \epsilon}{\partial \sigma} = \frac{1}{E_t} = b + 2c\sigma + 3d\sigma^2$$

The actual procedure is discussed more fully in Appendix B. Also in Appendix B is a listing of Subroutine MATCON which the user must modify by incorporating the tangent modulus as a function of the stress.

The finite element model (Figure 2) considers only one-quarter of the specimen geometry (See Figure 1) since symmetry can be used to reduce the problem size. The boundary conditions, coordinate axis, and loading are also indicated in Figure 2. Appendix C contains several enlarged areas of Figure 2 along with element and node numbers for the convenience of the reader.

The input data echo from CREEP-PLAST is contained in Appendix D. Appendix D, along with Appendix C provides a complete description of the finite element model.

Figure 2 CREEP-PLAST Finite Element Model with Boundary Conditions

The particular load-time history used in this analysis is shown in Figure 3. The temperature was assumed to be a constant 85°F throughout the analyses.

Since the CREEP-PLAST finite element code can handle only mono-modulus (that is, either tension or compression, but not both) type properties, it was necessary to choose either tension or compression creep properties for the analysis. The material constants used in the elastic constitutive relations (i.e., E , ν) are very nearly the same for tension and compression, however, as can be seen from Figures A-1 and A-2 of Appendix A, the creep behavior in tension or compression is quite different. Since the important material behavior of load-time dependent relaxation of residual stresses occurs as a result of an applied tensile load, it was somewhat arbitrarily decided to use the creep properties corresponding to the 85°F tension creep tests. In examining the impact of this decision on the results of this analysis, it can generally be concluded that the significant effect of load-time dependent relaxation of residual stresses will still be observed, however, the magnitude of total strain relaxation may be different. In particular note that load-time dependent relaxation of residual stresses will occur in a relatively short time period and thus the secondary creep term ($\dot{\epsilon}_{mt}$) will be negligible. Also note that the primary creep rate (r) is the same for tension and compression. Thus the difference between tension and compression creep behavior for small time is due to the quantity ϵ_t . This quantity effects the amount of residual strain relaxation, not the rate. Thus even though the choice of tension creep properties is somewhat arbitrary the basic conclusions will remain the same.

An examination of the first iteration, which is an elastic solution, shows that the stress concentration factor is approximately 2.5, which compares favorably with theoretical derivations for the stress concentration factor.

Figure 3 Applied Loading/Unloading Sequence

A plot of the total strain (TOTAL = ELASTIC + PLASTIC + CREEP) is shown in Figure 4 for $t < 87,000$ sec. It is observed that from about $t = 30$ sec. to $t = 6000$ sec., that load-time dependent relaxation of residual stress occurs. In particular at $t = 30$ sec. (start of continuously applied compressive load) the total (effective) strain is 8310μ in/in. At $t = 6000$ sec., the effective strain is 2682μ in/in. From $t = 6000$ sec., the behavior is quite clearly a result of creep strain under a compressive load with both primary and secondary creep in evidence.

The CREEP-PLAST code does not print out accumulated creep strain, however, shown in Figure 5 is a plot of the elastic strain and the non-elastic (plastic and creep) strain for the time period involved. After the initial relaxation period the accumulated strain is primarily due to creep. Appendix E contains the CREEP-PLAST code computer output for selected times.

III. CONCLUSIONS AND RECOMMENDATIONS

The analytical technique and results presented herein for the load-time dependent relaxation of residual stresses in an aluminum test specimen has been shown to be a valuable addition to the experimental work previously done in this area. This analysis is essentially a demonstration of the value of using an analytical approach in order to gain a better understanding of complex material behavior. However, as in all efforts of this nature, it is possible to improve the results.

Specifically, the following recommendations are made:

- (1) Determine by test within the same specimen lots the actual nonlinear stress-strain curve. Thus, creep test data will have an associated stress-strain curve. In this manner differences between handbook data (i.e., MIL-HDBK-5) and the actual specimen behavior are excluded from the analysis.
- (2) Utilize linear regression analysis to minimize any curve-fitting errors.
- (3) Consider code modifications to CREEP-PLAST in order to handle tension and compression properties. At the moment there is not a unified theory that considers the combined effects of multiaxial stresses and the effect on creep properties, so any modifications at this point would be somewhat empirical in nature.
- (4) Consider the possibility of load-time-temperature dependent relaxation of residual stresses. Such a consideration would involve a larger testing matrix to establish property trends as a function of temperature.

APPENDIX A

REDUCTION OF CREEP TEST DATA
FROM
ALUMINUM 7075 T651 TEST SPECIMEN

The creep test data (Ref. 6) used to establish the creep strain relations for CREEP-PLAST are shown in Tables A-1 through A-15. This data is for aluminum (7075 T651 bare) at two different temperatures (85°F and 135°F) and for varying stress levels in tension and compression. Since the current version of CREEP-PLAST can handle only mono-modulus type properties, only the 85°F tension creep test data is reduced and utilized in this analysis.

CREEP-PLAST requires that the creep strains be expressible in the following form:

$$\epsilon_c = \epsilon_t(1 - e^{-rt}) + \dot{\epsilon}_m t$$

where

ϵ_c = creep strain

ϵ_t = limiting creep strain for primary creep

r = exponential rate term

$\dot{\epsilon}_m$ = secondary creep strain rate

t = time

The quantities ϵ_t , $\dot{\epsilon}_m$ and r must be expressed as a function of the stress level for use in Subroutines MATCON and SHIFT (See Appendix B).

The first step in the data reduction is to plot the data of Tables A-1 through A-15. This plotting has been shown in Figures A-1 and A-2 along with the fitted curve used in CREEP-PLAST. To facilitate the determination of the quantities ϵ_t , $\dot{\epsilon}_m$ and r , the secondary creep strain rate has been estimated visually from Figures A-1 and A-2. By choosing two points in the primary creep region--say (ϵ_{c_1}, t_1) and (ϵ_{c_2}, t_2) --then two simultaneous equations can be

used to determine ϵ_t and r , thus,

$$\epsilon_{c_1} = \epsilon_t (1 - e^{-rt_1}) + \dot{\epsilon}_m t_1$$

$$\epsilon_{c_2} = \epsilon_t (1 - e^{-rt_2}) + \dot{\epsilon}_m t_2$$

from which, by trial and error, r can be found from

$$\frac{1 - e^{-rt_1}}{1 - e^{-rt_2}} = \frac{\epsilon_{c_1} - \dot{\epsilon}_m t_1}{\epsilon_{c_2} - \dot{\epsilon}_m t_2}$$

Knowing r , then ϵ_t can be found quite easily.

Although other methods for determining ϵ_t , $\dot{\epsilon}_m$ and r can be used (i.e., regression analysis to minimize error) this approach is sufficiently accurate for the purposes of this analysis.

The quantities ϵ_t , $\dot{\epsilon}_m$ and r , determined by the above approach, are shown in Table A-16.

Next, it is necessary to express the quantities ϵ_t , $\dot{\epsilon}_m$ and r as functions of stress. This was accomplished by assuming that either a straight line or a functional of the form

$$\epsilon_t, \dot{\epsilon}_m, r = a + b\sigma + c\sigma^2 + d\sigma^3$$

can be used to give an adequate fit to the data. The curves, along with the data points from Table A-16 are shown in Figure A-3. Since the trend for r is not well defined, a value of $r = 2.0 \times 10^{-4}/\text{sec}$ was used. The final equations are listed below (and are also included in Appendix B) for use in subroutines MATCON and SHIFT of the CREEP-PLAST code:

$$\sigma \leq 43,000 \text{ psi.} \quad \dot{\epsilon}_m = (6.325 \times 10^{-9})\sigma$$

$$43,000 < \sigma \leq 66,000 \text{ psi.} \quad \dot{\epsilon}_m = ((6.025 \times 10^{-9}) \\ + (6.569 \times 10^{-13})(\sigma - 43,000) + (2.668 \times 10^{-20}) \\ \times (\sigma - 43,000)^2)(\sigma - 43,000) + 2.591 \times 10^{-4}$$

$$66,000 < \sigma \leq 71,000 \text{ psi.} \quad \dot{\epsilon}_m = ((3.628 \times 10^{-8}) \\ + (2.293 \times 10^{-11})(\sigma - 66,000))(\sigma - 66,000) + 7.455 \times 10^{-4}$$

$$\sigma > 71,000 \quad \dot{\epsilon}_m = (1.8 \times 10^{-6})(\sigma - 71,000) + 1.5 \times 10^{-3}$$

$$\sigma \leq 66,000 \quad \epsilon_t = (2.045 \times 10^{-3})\sigma$$

$$66,000 < \sigma \leq 72,000 \quad \epsilon_t = ((2.045 \times 10^{-3}) + (3.875 \times 10^{-7}) \\ \times (\sigma - 66,000) + (2.041 \times 10^{-9})(\sigma - 66,000)^2)(\sigma - 66,000) + 135$$

$$\sigma > 72,000 \quad \epsilon_t = (2.271 \times 10^{-1})(\sigma - 72,000) + 602.1$$

$$\text{for all } \sigma \geq 0 \quad r = 2.0 \times 10^{-4} / \text{sec}$$

CREEP-PLAST Code

APPENDIX B

LISTING OF SUBROUTINES
MATCON AND SHIFT

In using CREEP-PLAST, the user must modify two sub-routines to reflect the material being used in the analysis. Subroutine SHIFT contains the description of the material creep characteristics according to the relation

$$\epsilon_c = \epsilon_t(1 - e^{-rt}) + \dot{\epsilon}_m t$$

as discussed in Appendix A. The listing of subroutine SHIFT shown in Figure B-1 reflects the equations as presented in Appendix A.

Subroutine MATCON (Figure B-2) contains a description of the stress-strain curve including the tangent modulus as a function of the effective stress. The stress-strain curve used is taken from MIL-HDBK-5 and reproduced in Figure B-3.

For this analysis the stress-strain curve corresponding to LT tension has been used. Using a quadratic function in terms of the effective stress yields the following:

$$\begin{aligned} \text{for } \sigma \leq 61,300 \text{ psi } \epsilon &= (9.788 \times 10^{-8})\sigma \\ \text{for } 61,300 < \sigma \leq 76,000 \text{ psi} \\ \epsilon &= (9.788 \times 10^{-8})\sigma + (5.873 \times 10^{-12})\sigma^2 \\ &\quad + (3.539 \times 10^{-16})\sigma^3 \\ \text{for } \sigma > 76,000 \text{ psi } \epsilon &= (5.0 \times 10^{-7})\sigma \end{aligned}$$

For the tangent modulus

$$\begin{aligned} \text{for } \sigma \leq 61,300 \text{ } E_t &= 10.22 \times 10^6 \text{ psi} \\ \text{for } 61,300 < \sigma \leq 76,000 \text{ psi} \\ E_t &= 1/(9.788 \times 10^{-8}) + (1.175 \times 10^{-11})\sigma \\ &\quad + (1.062 \times 10^{-15})\sigma^2 \end{aligned}$$

and for $\sigma > 76,000$ psi.

$$E_t = 2.0 \times 10^6 \text{ psi}$$

These equations have been incorporated into subroutine MATCON.

Figure B-2 (continued)

As a result of a coding error in subroutine SHIFT (not shown) a slightly different equation for the tangent modulus as a function of stress was used. In particular

$$\sigma < 76,000 \text{ psi.} \quad E_t = 10.22 \times 10^6 \text{ psi.}$$

$$\sigma \geq 76,000 \text{ psi.} \quad E_t = 2.00 \times 10^6 \text{ psi.}$$

This is a bilinear curve slightly "higher" than the LT-tension curve of Figure B-3. The difference between this bilinear curve used and the LT-tension curve is negligible (< 5%) as far as the effective stress-effective strain coordinates at the start of continuous compressive load is concerned. The formulation of the LT-tension curve is retained in this report in order to show clearly the technique used to represent the tangent modulus as a function of the effective stress.

Figure B-3 Stress-strain curve for Aluminum 7075 T651 used in analysis (LT-Tension used) and taken from MIL-HDBK-5

APPENDIX C

FINITE ELEMENT MODEL OF ALUMINUM
CREEP TEST SPECIMEN

The finite element grid used in the CREEP-PLAST analysis is shown in Figure C-1 and C-2. This model is one-quarter of the aluminum specimen since symmetry has been used to decrease the model size. Boundary conditions are discussed in the text. Detailed input data corresponding to the grid is included in Appendix D. Included in this section is an additional listing of the nodal point coordinates for the convenience of the user.

APPENDIX D

LISTING OF DATA INPUT FOR
FINITE ELEMENT CODE CREEP-PLAST

This appendix presents the input data used for executing the CREEP-PLAST code. Notice that nodal data is printed in a format that does not include all the significant digits of the coordinates. However, Appendix C contains the card images for the nodal points and elements from which exact nodal coordinates can be found. The output presented here is for the initial run using CREEP-PLAST.

APPENDIX E

PARTIAL LISTING OF COMPUTER OUTPUT
FROM CREEP-PLAST

In this appendix is presented the output from the code CREEP-PLAST corresponding to Figures 4 and 5 in Section II. Since quite a voluminous amount of output is generated only the more important time steps have been included. The entire output is available upon request. Note that times in this output are "seconds" and not "hours". The output for the following time steps have been included in this Appendix:

<u>Time Step No.</u>	<u>Time (sec.)</u>
1	7.0
32	30.0
43	1,000.0
44	2,000.0
45	3,000.0
46	4,000.0
47	5,000.0
48	6,000.0
49	7,000.0
50	8,000.0
51	9,000.0
52	10,000.0
62	20,000.0
72	30,000.0
91	50,000.0
105	80,000.0

← not here

TIME 1 = 7.000HOURS AT PRESSURE = .4670 0.0000 0.0000 AND AT TEMPERATURE = 1.0000

OUTPUT TAPE 9 HAS BEEN UPDATED THROUGH TIME STEP 72

INPUT TAPE 14 CONTAINS TIME STEP 40

RESTART NEXT RUN EITHER FROM TIME STEP 73 USING 9 AS INPUT TAPE, OR FROM TIME STEP 14 USING 14 AS INPUT TAPE
THE PROBLEM CAN BE REINITIALIZED BY SIMPLY SETTING N7=2 AND REDEFINING THE DIM(1) ARRAY
ALL OTHER PARAMETERS HAVE THE SAME MEANING AS IN A NORMAL RESTART RUN

TIME LOG FOR PROBLEM (SECONDS)

TIME 91 = 50000.000HOURS AT PRESSURE = -.1670 0.0000 0.0000 AND AT TEMPERATURE= 1.0000

NODAL POINT R-DISPLACEMENT Z-DISPLACEMENT
